## AP Chemistry Exam II <br> Part II: Essays. Show ALL work below. Work should be done in a clear and orderly fashion.

## Free Response \#1

(a) Write a balanced equation for the complete combustion of butane $\left(\mathrm{C}_{4} \mathrm{H}_{10}\right)$ gas, which yields $\mathrm{CO}_{2}(\mathrm{~g})$ and $\mathrm{H}_{2} \mathrm{O}(\mathrm{l})$
(b) Calculate the volume of air at $29^{\circ} \mathrm{C}$ (probably the temp currently in the classroom: $84^{\circ} \mathrm{F}$ ) and 1.01 atmosphere (current pressure at my house) that is needed to burn completely 227 grams of butane (one full can). Assume that air is 21.0 percent $\mathrm{O}_{2}$ by volume.
(c) The heat of combustion of butane is $-2,877 \mathrm{~kJ} / \mathrm{mol}$. Calculate the heat of formation, $\Delta \mathrm{H}^{\circ}$, of butane given that $\Delta \mathrm{H}^{\circ}$ of $\mathrm{H}_{2} \mathrm{O}(\mathrm{l})=-285.3 \mathrm{~kJ} / \mathrm{mol}$ and $\Delta \mathrm{H}_{\mathrm{f}}^{\circ}$ of $\mathrm{CO}_{2}(\mathrm{~g})=-393.5 \mathrm{~kJ} / \mathrm{mol}$.
(d) If the combustion of one mole of butane produces $2877 \mathrm{~kJ} / \mathrm{mol}$ of heat. How much heat will be produced by 40.0 grams of butane.
(e) Assuming that all of the heat evolved in burning 40.0 grams of butane is transferred to 18.00 kilograms of water (specific heat $=4.184 \mathrm{~J} / \mathrm{g} \times \mathrm{K}$ ), calculate the increase in temperature of the water.
(f) In a separate experiment 40.0 grams of butane was combusted and the gas was collected over water in a 19.0 liter metal canister at $88.0^{\circ} \mathrm{C}$. Calculate the total pressure if the vapor pressure of water at $88.0^{\circ} \mathrm{C}$ is 487 torr.

## Free Response \#2

A student was assigned the task of determining the molar mass of an unknown gas. The student measured the mass of a sealed 803 mL rigid flask that contained dry air. The student then flushed the flask with the unknown gas, resealed it, and measured the mass again. Both the air and the unknown gas were at $20.0^{\circ} \mathrm{C}$ and 767 . torr.

The data for the experiment are shown in the table below.

| Volume of sealed flask | 803 mL |
| :---: | :---: |
| Mass of sealed flask and dry air | 156.70 g |
| Mass of sealed flask and unknown gas | 158.08 g |

(a) Calculate the mass, in grams, of the dry air that was in the sealed flask. (The density of dry air is $1.2152 \mathrm{~g} \mathrm{~L}^{-1}$ at $20.0^{\circ} \mathrm{C}$ and 767 . torr.)
(b) Calculate the mass, in grams, of the sealed flask itself (i.e., if it had no air in it).
(c) Calculate the mass, in grams, of the unknown gas that was added to the sealed flask.
(d) Using the information above, calculate the value of the molar mass of the unknown gas.

After the experiment was completed, the instructor informed the student that the unknown gas was sulfur dioxide.
(e) Calculate the percent error in the value of the molar mass calculated in part (d).
(f) For each of the following two possible occurrences, indicate whether it by itself could have been responsible for the error in the student's experimental result. You need not include any calculations with your answer. For each of the possible occurrences, justify your answer.

Occurrence 1: The temperature of the air was $20.0^{\circ} \mathrm{C}$, but the temperature of the $\mathrm{SO}_{2}(g)$ was lower than the reported $20.0^{\circ} \mathrm{C}$.
Occurrence 2: The flask was incompletely flushed with $\mathrm{SO}_{2}(g)$, resulting in some dry air remaining in the flask.

## Free Response \#3

An 5.560 mol sample of methanol, $\mathrm{CH}_{3} \mathrm{OH}$, is placed in a 6.00 L evacuated rigid tank and heated to $369^{\circ} \mathrm{C}$. At that temperature all of the methanol is vaporized and some of the methanol decomposes to form carbon monoxide gas and hydrogen gas, as represented in the equation: $\mathrm{CH}_{3} \mathrm{OH}(\mathrm{g}) \rightleftharpoons \mathrm{CO}(\mathrm{g})+2 \mathrm{H}_{2}(\mathrm{~g})$
(a) The reaction mixture contains 3.968 mol of $\mathrm{CO}(\mathrm{g})$ at equilibrium at $369^{\circ} \mathrm{C}$.
(i) Calculate the number of moles of $\mathrm{H}_{2}(g)$ in the tank.
(ii) Calculate the number of grams of $\mathrm{CH}_{3} \mathrm{OH}(\mathrm{g})$ remaining in the tank.
(iii) Calculate the mole fraction of $\mathrm{H}_{2}(\mathrm{~g})$ in the tank.
(iv) Calculate the total pressure, in atm, in the tank at $369^{\circ} \mathrm{C}$.
(b) Consider the three gases in the tank at $369^{\circ} \mathrm{C}: \mathrm{CH}_{3} \mathrm{OH}(\mathrm{g}), \mathrm{CO}(\mathrm{g})$, and $\mathrm{H}_{2}(\mathrm{~g})$.
(i) Calculate the average root mean square velocity of the molecules of each gas.
(ii) If the temperature was raised from $369^{\circ} \mathrm{C}$ to $693^{\circ} \mathrm{C}$ determine the new velocity of $\mathrm{CH}_{3} \mathrm{OH}(\mathrm{g})$ gas.
(c) Write the equilibrium expression for the expression and calculate $\mathrm{K}_{\mathrm{c}}$ at $369^{\circ} \mathrm{C}$.
(d) Calculate $\mathrm{K}_{\mathrm{p}}$ based on $\mathrm{K}_{\mathrm{c}}$ at $369^{\circ} \mathrm{C}$.

## Free Response \#4

At elevated temperatures, $\mathrm{NH}_{3}$ gas decomposes into $\mathrm{N}_{2}$ gas and $\mathrm{H}_{2}$ gas.
(a) Write the balanced reversible equation for this reaction.
(b) A 27.0 gram sample of $\mathrm{NH}_{3}$ is placed in an evacuated 20.0-liter container at $381.6^{\circ} \mathrm{C}$.
(i) What is the concentration in moles per liter of $\mathrm{NH}_{3}$ in the container before any decomposition occurs?
(ii) What is the pressure in atmospheres of $\mathrm{NH}_{3}$ in the container before any decomposition occurs?
(c) If the $\mathrm{NH}_{3}$ is 25.80 percent decomposed when equilibrium is established at $381.6^{\circ} \mathrm{C}$, calculate the value for the concentration equilibrium constant, $\mathrm{K}_{\mathrm{c}}$, for this decomposition reaction.
(d) Calculate the pressures equilibrium constant, $\mathrm{K}_{\mathrm{p}}$.
(e) In order to produce some $\mathrm{NH}_{3}$, a 3.75-mole sample of $\mathrm{N}_{2}$ is first placed in an empty 3.00-liter container maintained at a temperature different from $381.6^{\circ} \mathrm{C}$. At this temperature $\mathrm{K}_{\mathrm{c}}$ equals 0.220 . How many moles of $\mathrm{H}_{2}$ must be added to this container to reduce the number of moles of $\mathrm{N}_{2}$ to 0.700 mole at equilibrium?
